研究背景 (Background)

The Rh blood group system is the second most clinically significant of the blood groups, second only to ABO. It is also the most polymorphic of the blood groups, with variations due to deletions, gene conversions, and missense mutations. The Rh blood

group includes this gene, which encodes the RhD protein, and a second gene that encodes both the RhC and RhE antigens on a single polypeptide. The two genes, and a third unrelated gene, are found in a cluster on chromosome 1. The classification of Rh-positive and Rh-negative individuals is determined by the presence or absence of the highly immunogenic RhD protein on the surface of erythrocytes. Multiple transcript variants encoding different isoforms have been found for this gene. [provided by RefSeq, Jul 2008],function:May be part of an oligomeric complex which is likely to have a transport or channel function in the erythrocyte membrane.,online information:Blood group antigen gene mutation database,polymorphism:RHD and RHCE are responsible for the Rh blood group system. The molecular basis of the Tar=Rh40 blood group antigen is a polymorphism in position 110.,similarity:Belongs to the ammonium transporter (TC 2.A.49) family. Rh subfamily.,tissue specificity:Restricted to tissues or cell lines expressing erythroid characters.,
