研究背景 (Background)

This gene is one of seven beta-1,4-galactosyltransferase (beta4GalT) genes. They encode type II membrane-bound glycoproteins that appear to have exclusive specificity for the donor substrate UDP-galactose; all transfer galactose in a beta1,4 linkage to similar acceptor sugars: GlcNAc, Glc, and Xyl. Each beta4GalT has a distinct function in the biosynthesis of different glycoconjugates and saccharide structures. As type II membrane proteins, they have an N-terminal hydrophobic signal sequence that directs the protein to the Golgi apparatus and which then remains uncleaved to function as a transmembrane anchor. By sequence similarity, the beta4GalTs form four groups: beta4GalT1 and beta4GalT2, beta4GalT3 and beta4GalT4, beta4GalT5 and beta4GalT6, and beta4GalT7. This gene encodes an enzyme that may be mainly involved in the synthesis of the first N-acetylactosamine unit of poly-N-acetylactosamine. $\text{UDP-galactose} + \text{N-acetyl-beta-D-glucosaminylglycopeptide} = \text{UDP} + \text{beta-D-galactosyl-(1-4)-N-acetyl-beta-D-glucosaminylglycopeptide}$, catalytic activity: $\text{UDP-galactose} + \text{N-acetyl-D-glucosamine} = \text{UDP} + \text{N-acetylactosamine}$, cofactor: Manganese, function: Responsible for the synthesis of complex-type N-linked oligosaccharides in many glycoproteins as well as the carbohydrate moieties of glycolipids, online information: Beta-1,4-galactosyltransferase 3, online information: GlycoGene database, pathway: Protein modification; protein glycosylation, similarity: Belongs to the glycosyltransferase 7 family, subcellular location: Trans cisternae of Golgi stack, tissue specificity: Found in various tissues. Highest expression in placenta, prostate, testis, ovary, intestine and muscle, and in fetal brain,
